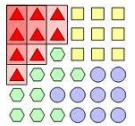
Data Warehousing and Data Mining

Unit 2

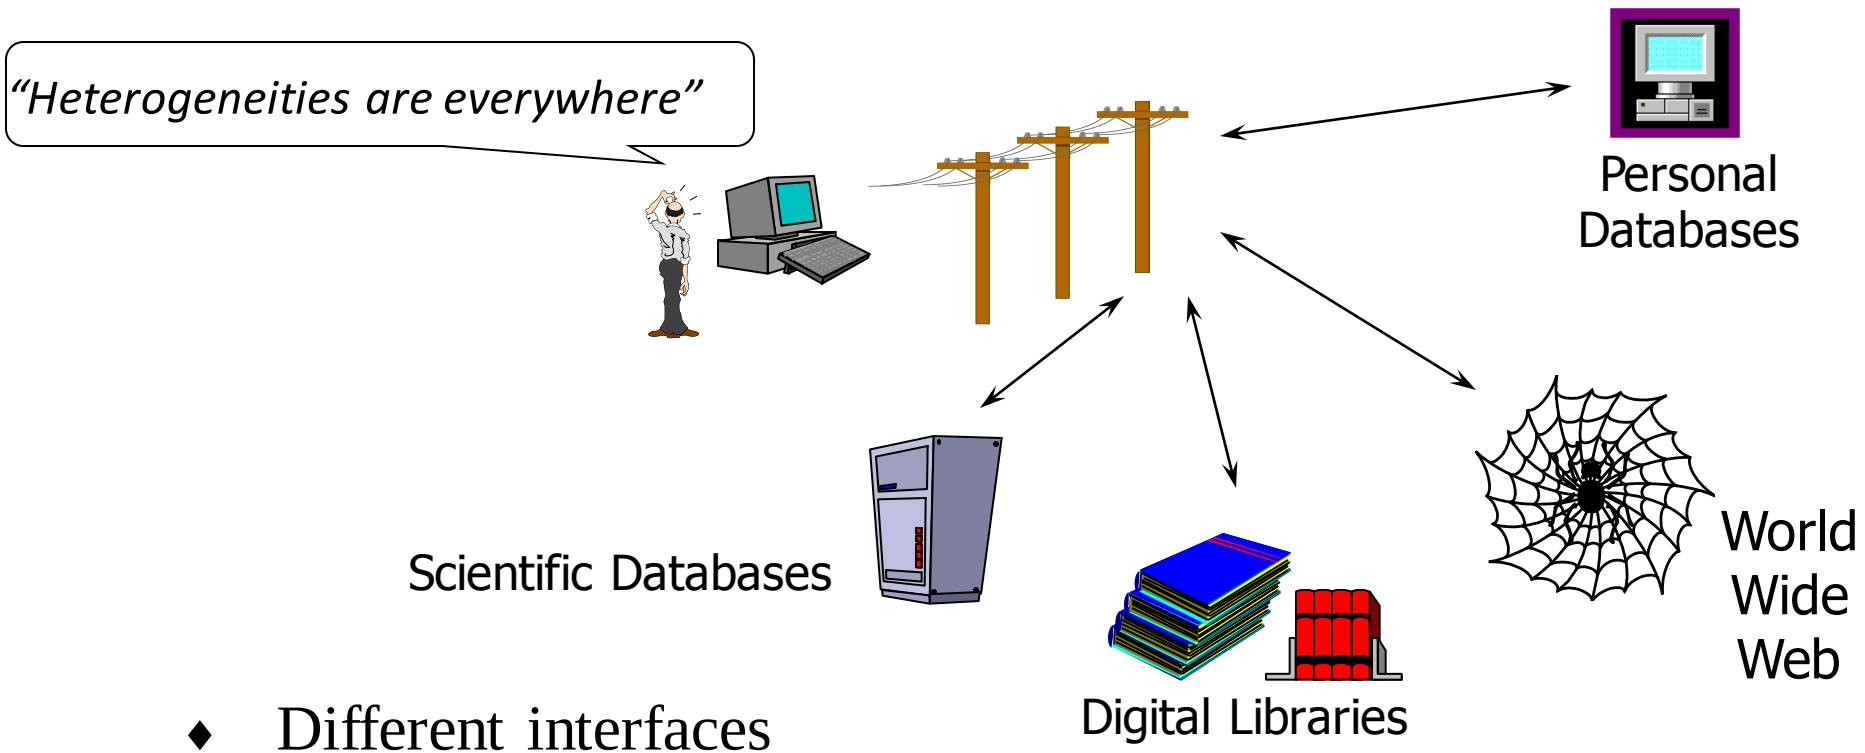
Instructor
Suresh Pokharel

Content



- DBMS vs. Data Warehouse
- Data marts and Metadata,
- Multidimensional data model
- Data Cubes
- Schemes : Stars, Snowflakes and Fact Constellations.

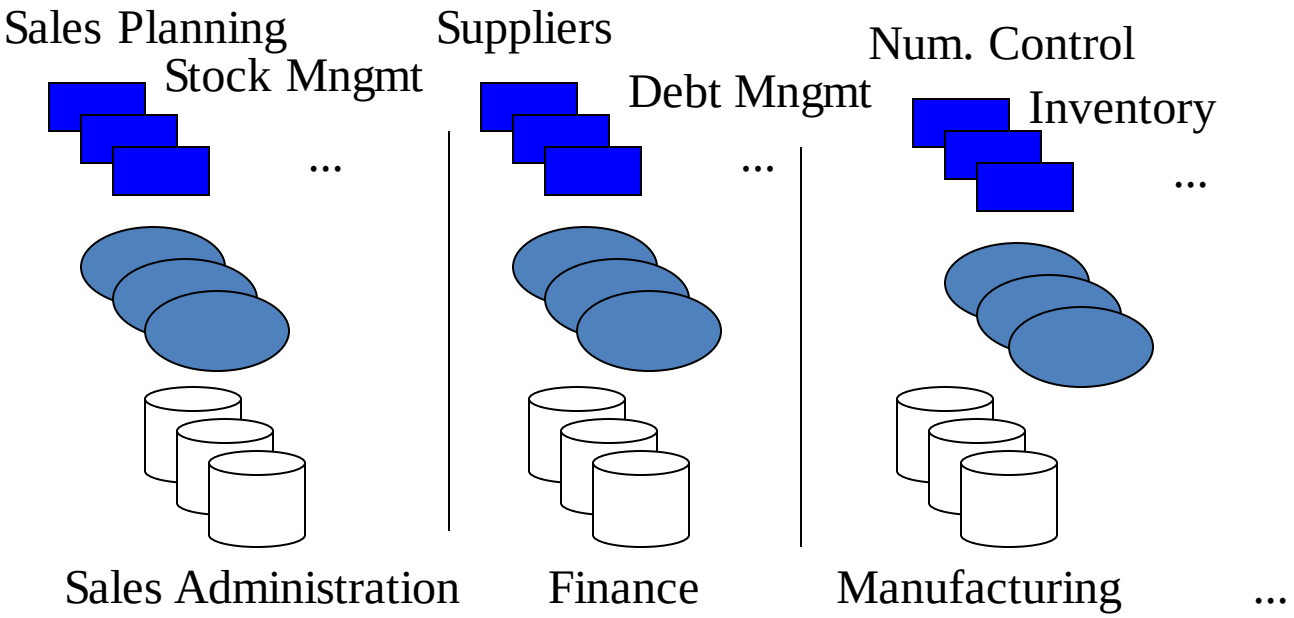
Problem: Heterogeneous Information Sources



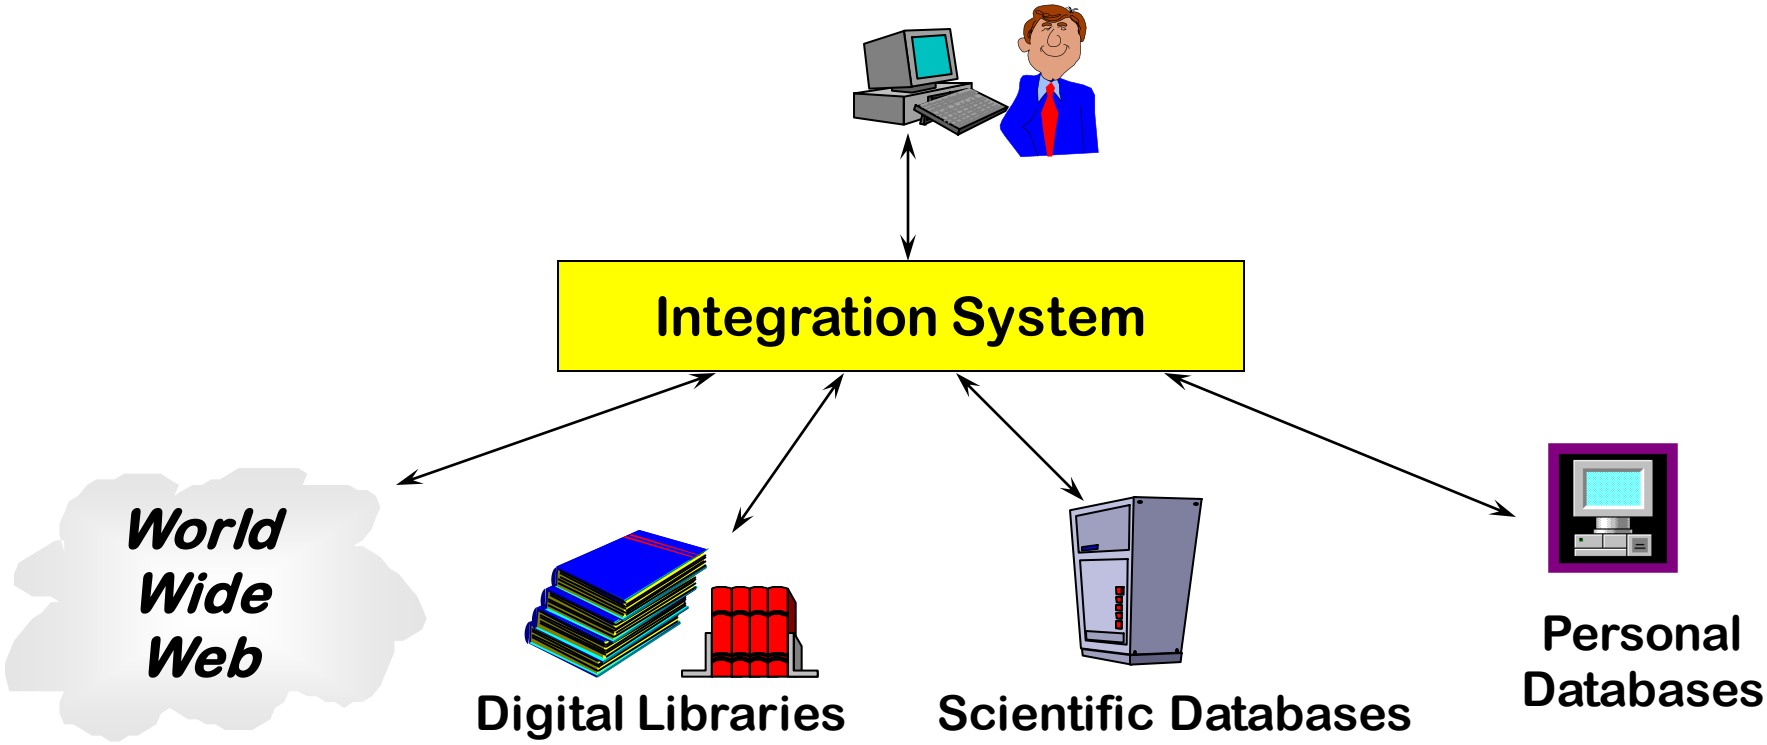
- Different interfaces
- Different data representations
- Duplicate and inconsistent information

Problem: Data Management in Large Enterprises

- Vertical fragmentation of informational systems (vertical stove pipes)

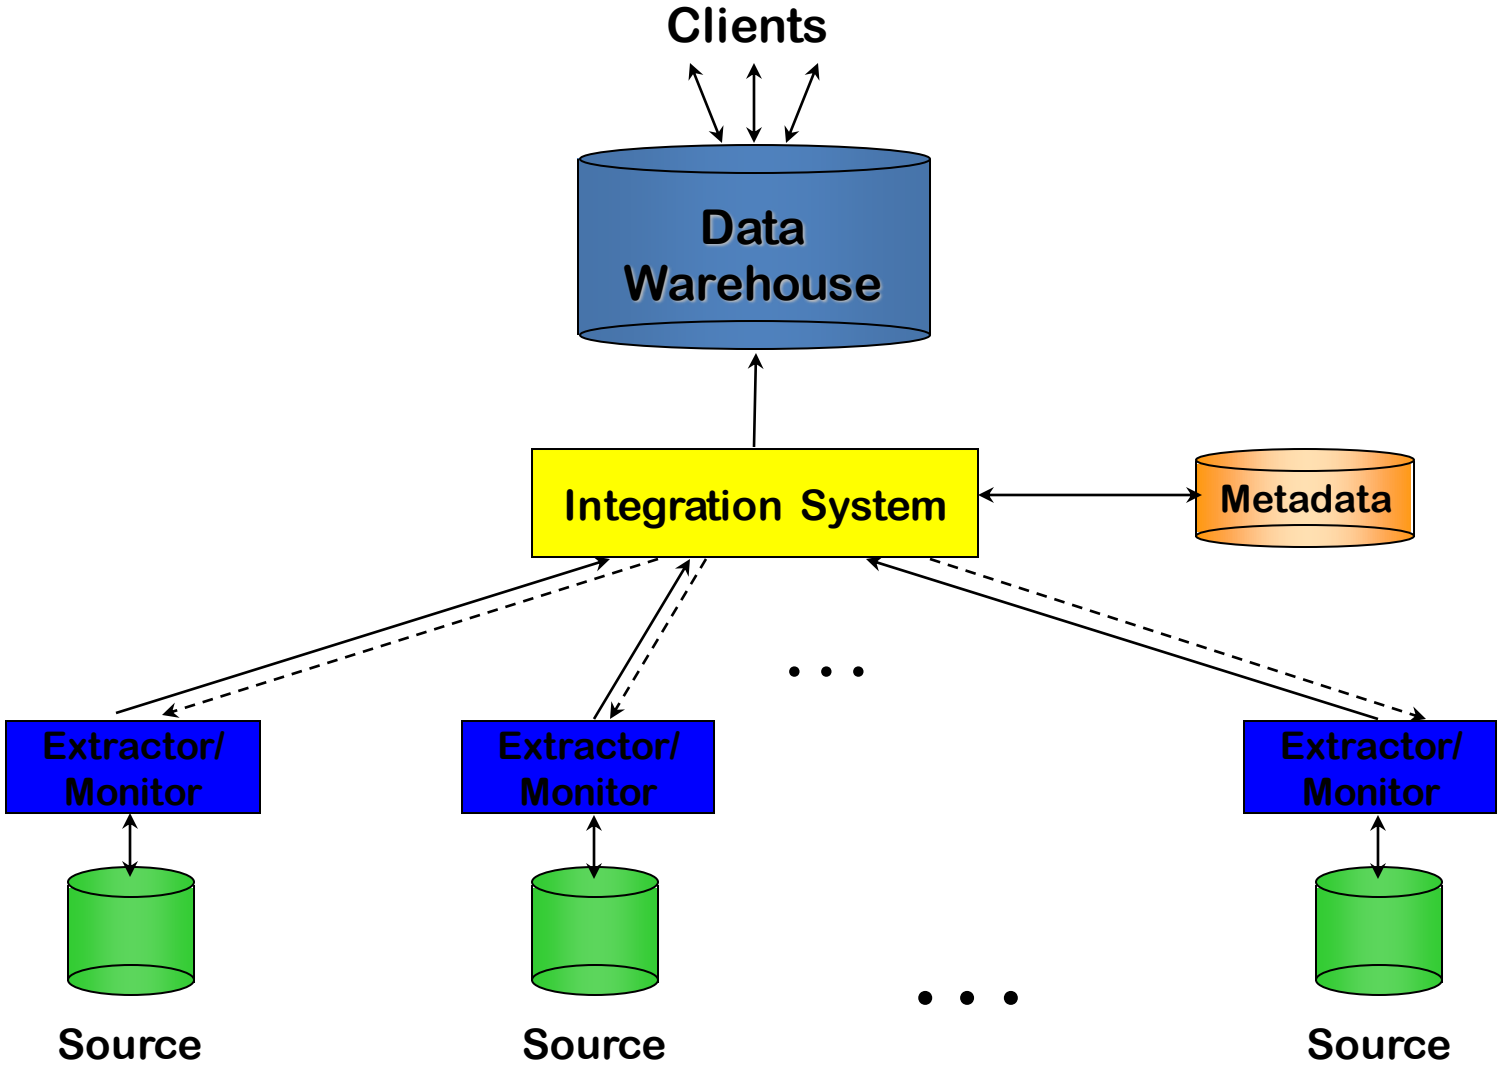


Goal: Unified Access to Data

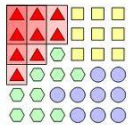


- Collects and combines information
- Provides integrated view, uniform user interface
- Supports sharing

The Warehouse

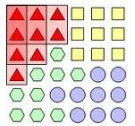


What is Data Warehouse?



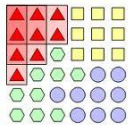
- Defined in many different ways:
  - A decision support database that is maintained separately from the organization's operational database
  - Support information processing by providing a solid platform of consolidated, historical data for analysis.
- "A data warehouse is a subject-oriented, integrated, time-variant, and nonvolatile collection of data in support of management's decision-making process."—W. H. Inmon
- Data warehousing:
  - The process of constructing and using data warehouses

Data Warehouse—Subject-Oriented



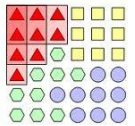
- Organized around major subjects, such as customer, product, sales.
- Focusing on the modeling and analysis of data for decision makers, not on daily operations or transaction processing.
- Provide a simple and concise view around particular subject issues by excluding data that are not useful in the decision support process.

Data Warehouse—Integrated



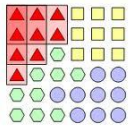
- Constructed by integrating multiple, heterogeneous data sources
  - relational databases, flat files, on-line transaction records
- Data cleaning and data integration techniques are applied.
  - Ensure consistency in naming conventions, encoding structures, attribute measures, etc. among different data sources
    - E.g., Hotel price: currency, tax, breakfast covered, etc.
  - When data is moved to the warehouse, it is converted.

Data Warehouse—Time Variant



- The time horizon for the data warehouse is significantly longer than that of operational systems.
  - Operational database: current value data.
  - Data warehouse data: provide information from a historical perspective (e.g., past 5-10 years)

Data Warehouse—Non-Volatile

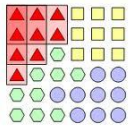


- A physically separate store of data transformed from the operational environment.
- Operational update of data does not occur in the data warehouse environment.
  - Does not require transaction processing, recovery, and concurrency control mechanisms
  - Requires only two operations in data accessing:
    - *initial loading of data* and *access of data*.

Data Warehouse & Operational Database

	Data Warehouse	Operational Database
Purpose	Analysis, Decision making, archival, and security purposes	Storage of database content, creation / maintenance of data, search and other functionalities
Support For	OLAP(on-line analytical processing)	OLTP(on-line transaction processing)
Data model	Multi-dimentional	Rational
Age of data	Current & time series	Current & real time
Data modification	Read/access only	Insert, update, delete
Type of data	Static	Dynamic
Amount of data per transaction	Larger	Smaller
Schema design	Denormalization	normalization

Data Warehouse and data Mart



Data warehouse: **enterprise based,** collects all information about subjects (*customers, products, sales, assets, personnel*) that span the entire organization

- Concerns with decision subjects of the whole enterprise or organization
- Requires extensive business modeling (may take years to design and build)

Data mart: **department based,** Departmental subsets that focus on selected subjects

- Specialized single line of business warehouses e.g. within departments or groups of people
- Marketing data mart: customer, product, sales

Data Warehouse Metadata

MAPPING

A basic part of the data warehouse environment is that of mapping from the ope
environment into the data warehouse. The mapping includes a wide variety of fa
including, but not limited to:

- mapping from one attribute to another,
- conversions,
- changes in naming conventions,
- changes in physical characteristics of data,
- filtering of data, etc.

Figure 3 shows the storing of the mapping in metadata for the data warehouse.

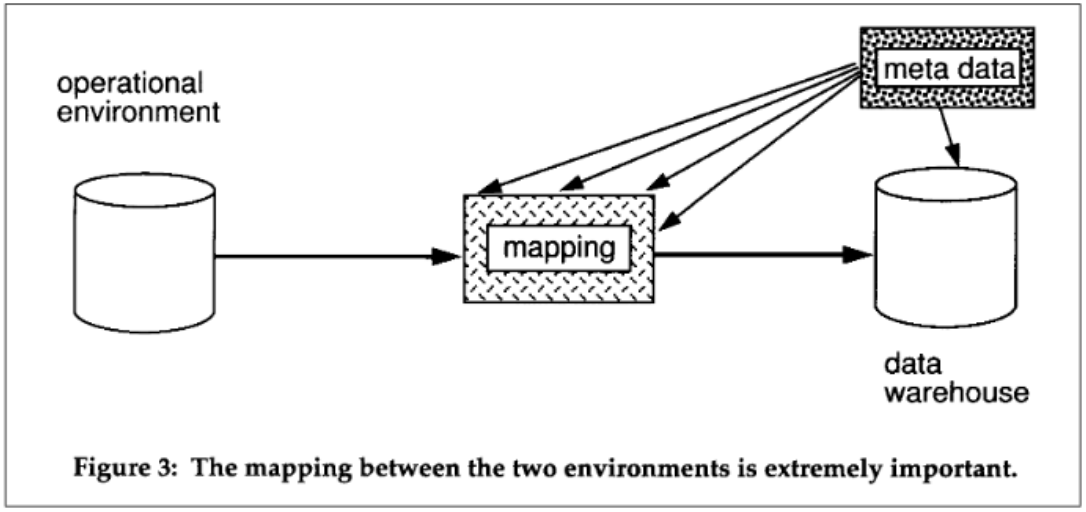


Figure 3: The mapping between the two environments is extremely important.

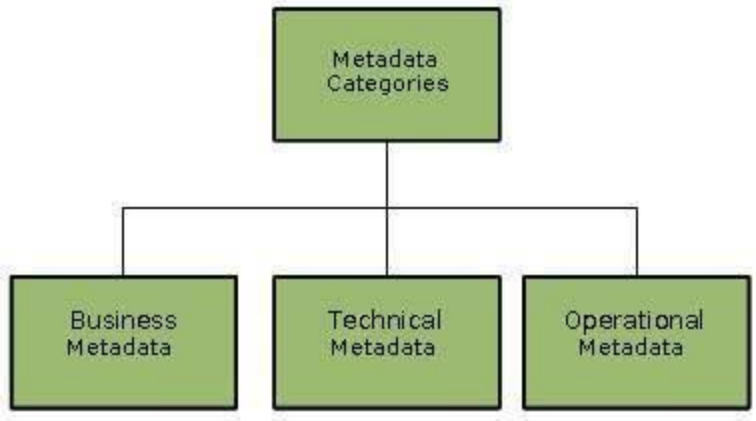
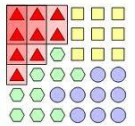
Categories of Metadata



- **Business Metadata** - It has the data ownership information, business definition, and changing policies.
- **Technical Metadata** - It includes database system names, table and column names and sizes, data types and allowed values. Technical metadata also includes structural information such as primary and foreign key attributes and indices.
- **Operational Metadata** - It includes currency of data and data lineage. Currency of data means whether the data is active, archived, or purged. Lineage of data means the history of data migrated and transformation applied on it.

Multidimensional Data Model

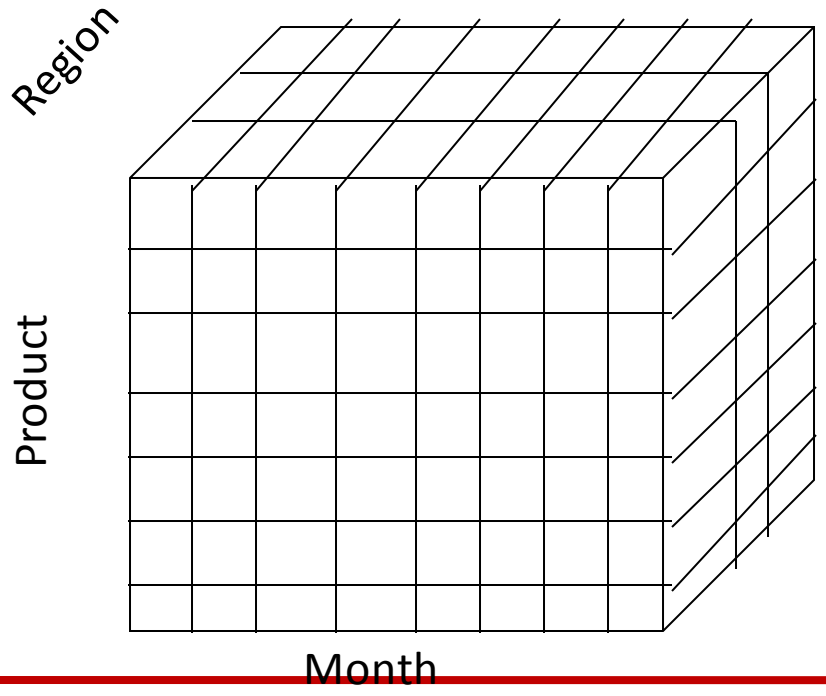


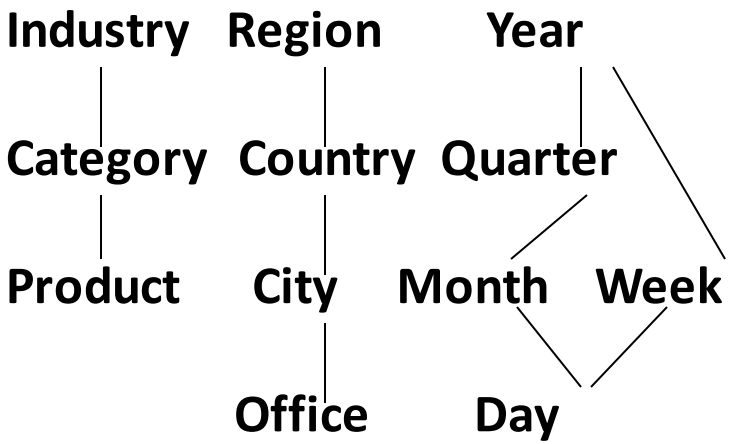
- Ex: data warehouse for a grocery store company,
- Each transaction contains which product at what time.
- The goods price and sold item amounts are called numeric measures that are the objects of analysis in a multidimensional data model.
- Categorical attributes : product, date, and region are called dimensions .
- Each of the numeric measures depends on a set of dimensions and the dimensions together are assumed to uniquely determine the measure. Thus the multidimensional data views a measure as a value in the multidimensional space of dimensions

Multidimensional Data Model

- Sales volume as a function of product, month, and region

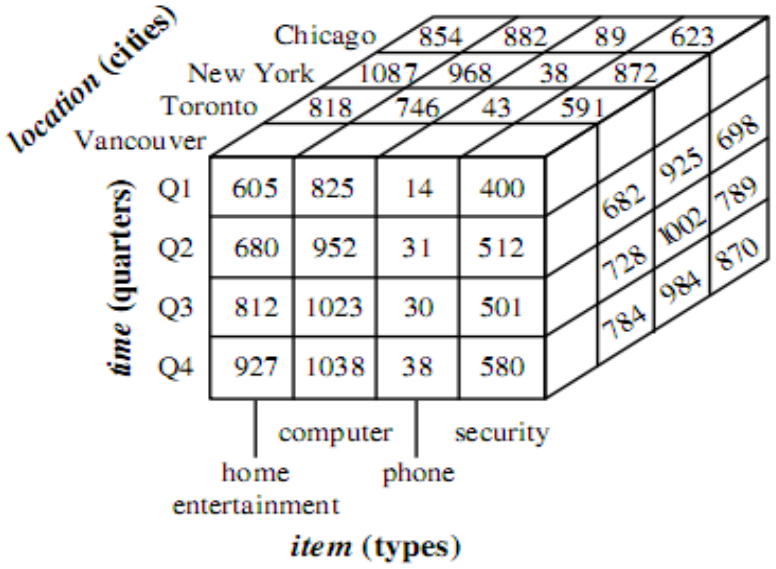
Dimensions: Product, Location, Time
Hierarchical summarization paths





3-D data cube representation from table

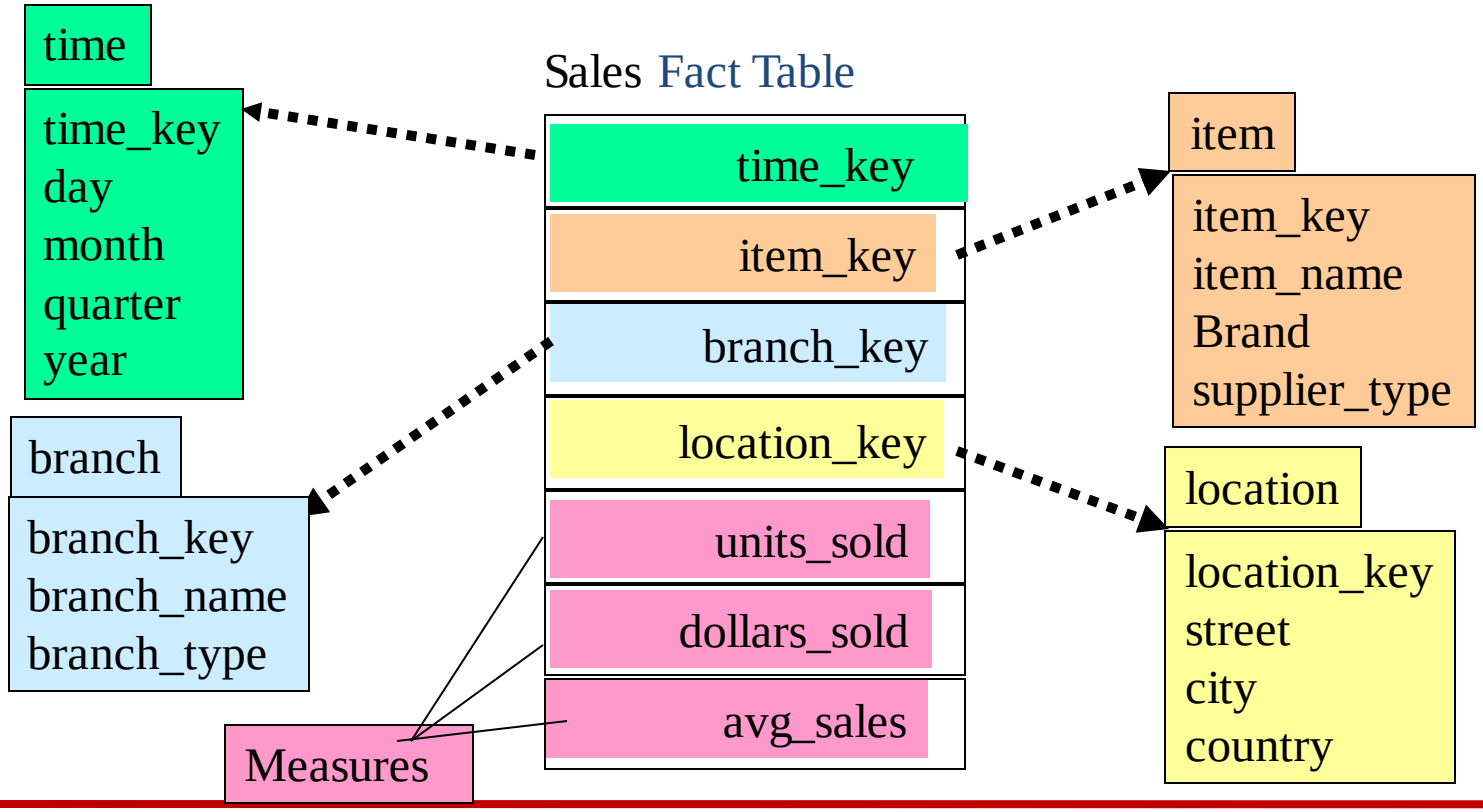
	location = "Chicago"				location = "New York"				location = "Toronto"				location = "Vancouver"			
	item				item				item				item			
time	home ent.	comp.	phone	sec.	home ent.	comp.	phone	sec.	home ent.	comp.	phone	sec.	home ent.	comp.	phone	sec.
Q1	854	882	89	623	1087	968	38	872	818	746	43	591	605	825	14	400
Q2	943	890	64	698	1130	1024	41	925	894	769	52	682	680	952	31	512
Q3	1032	924	59	789	1034	1048	45	1002	940	795	58	728	812	1023	30	501
Q4	1129	992	63	870	1142	1091	54	984	978	864	59	784	927	1038	38	580



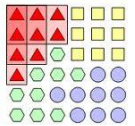
Conceptual Modeling of DW

- Dimensions & Measures

Star schema: A fact table in the middle connected to a set of dimension tables



Conceptual Modeling of DW



Snowflake schema

A refinement of star schema where some dimensional hierarchy is normalized into a set of smaller dimension tables, forming a shape similar to snowflake.

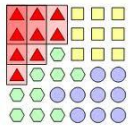
Conceptual Modeling of DW



Fact constellations:

Multiple fact tables share dimension tables, viewed as a collection of stars, therefore called galaxy schema or fact constellation

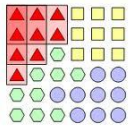
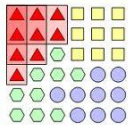
Measures

Decision Support System



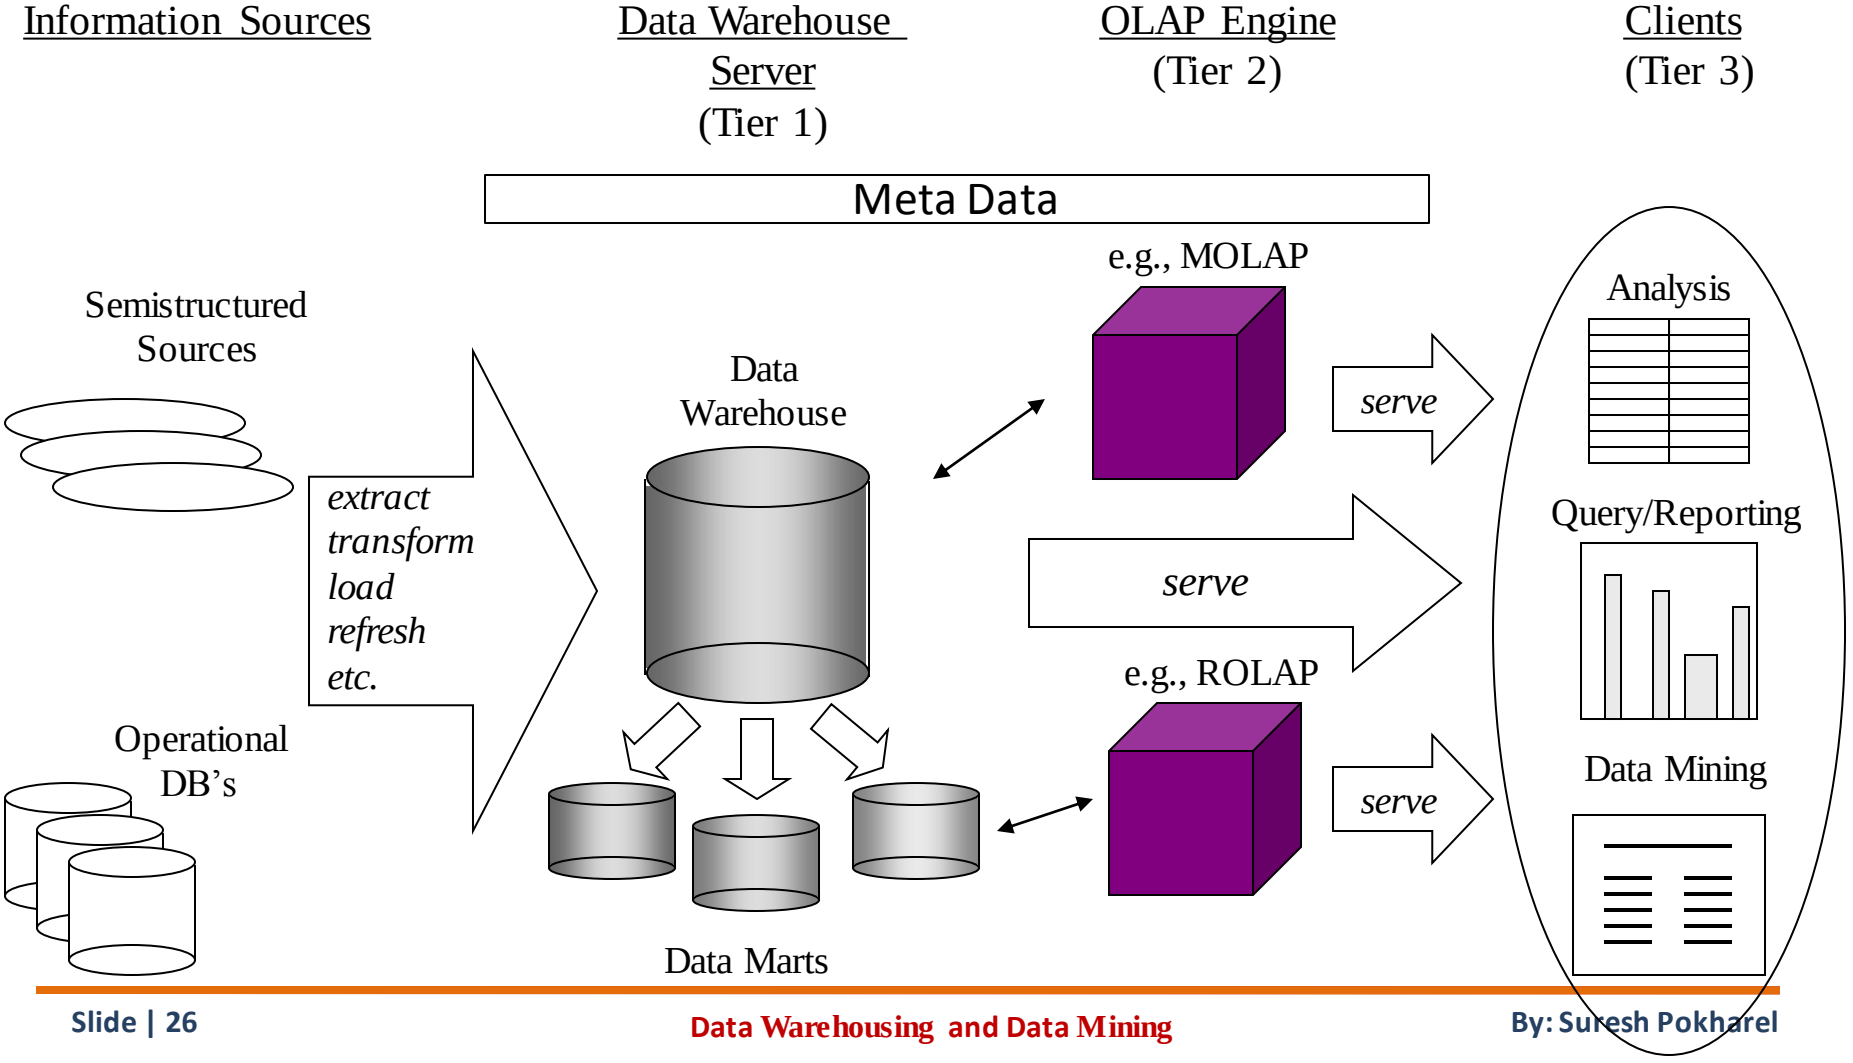
- Information technology to help the knowledge worker (executive, manager, analyst) make faster & better decisions
  - *"What were the sales volumes by region and product category for the last year?"*
  - *"How did the share price of comp. manufacturers correlate with quarterly profits over the past 10 years?"*
- On-line analytical processing (OLAP) is an element of decision support systems (DSS)



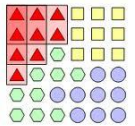
Three-Tier Decision Support Systems

- Warehouse database server
  - Almost always a relational DBMS, rarely flat files
- OLAP servers(p.p.135)
  - Relational OLAP (ROLAP): extended relational DBMS that maps operations on multidimensional data to standard relational operators
  - Multidimensional OLAP (MOLAP): special-purpose server that directly implements multidimensional data and operations
- Clients
  - Query and reporting tools
  - Analysis tools
  - Data mining tools

Data Warehouse Architecture



Approaches to OLAP Servers



- **Two possibilities for OLAP servers**

(1) Relational OLAP (ROLAP)

- Relational and specialized relational DBMS to store and manage warehouse data
- OLAP middleware to support missing pieces
- have greater scalability

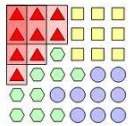
(2) Multidimensional OLAP (MOLAP)

- Array-based storage structures
- Direct access to array data structures
- Fast indexing to pre-computed summarized data

(3) Hybrid OLAP (HOLAP) server

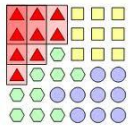
- Combine both ROLAP and MOLAP
- E.g. Microsoft SQL Server 2000

Data Preprocessing

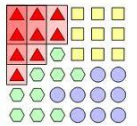


- Real world data : Noisy, missing and inconsistent (why??)
- Low quality data => Low quality mining result
- Data Cleaning
- Data integration
- Data transformations
- Data reduction

Data Cleaning



- Missing values
  - No record value for several attributes such as income
  - How can fill missing data?
  - E.g. manually, fill with mean, fill with probable
- Noisy Data
  - containing errors, or outlier values
  - How can smooth data ?
  - E.g. Binning, regression, clustering



Binning

Sorted data for *price* (in dollars): 4, 8, 15, 21, 21, 24, 25, 28, 34

Partition into (equal-frequency) bins:

Bin 1: 4, 8, 15
Bin 2: 21, 21, 24
Bin 3: 25, 28, 34

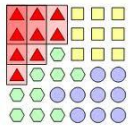
Smoothing by bin means:

Bin 1: 9, 9, 9
Bin 2: 22, 22, 22
Bin 3: 29, 29, 29

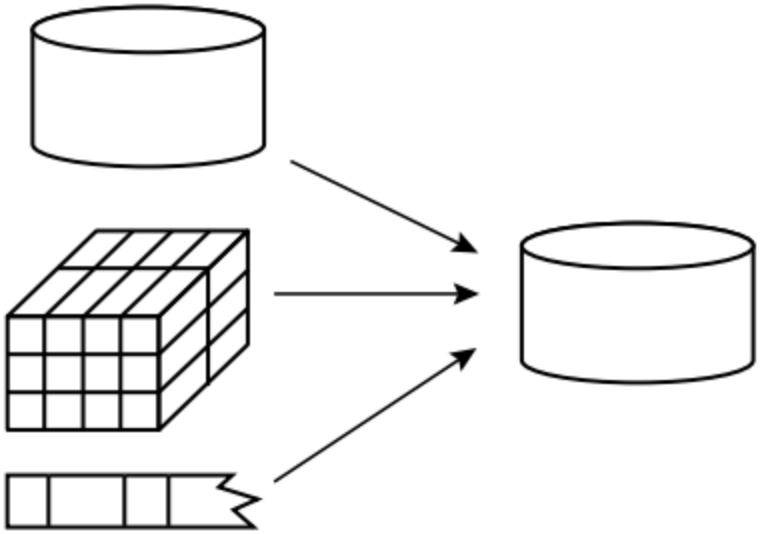
Smoothing by bin boundaries:

Bin 1: 4, 4, 15
Bin 2: 21, 21, 24
Bin 3: 25, 25, 34

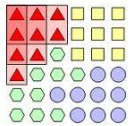
Data Integration



- Combines data from multiple sources(e.g. databases, data cubes or flat files) into data warehouse



Data Transformation



- Data transforms into appropriate form for mining
- Some of the methods:
- Smoothing: remove noise
- Aggregation : summary or aggregation operations are applied to the data.
- Generation : low-level =>high level concepts e.g. age => youth, middle-aged, senior
- Normalization : attribute data are scaled into specified range such as -1.0 to 1.0 or 0.0 to 1.0 (e. g. how??)

  e.g. $-2, 32, 100, 59, 48 \longrightarrow -0.02, 0.32, 1.00, 0.59, 0.48$

- Attribute construction : New features are constructed and added from the given set of attributes to help the mining process

Data Reduction

- Goal : Making mining process more efficient with out losing quality
- E.g.
